Through this course I have learned to build and migrate a scalable full-stack application to cloud services. This was accomplished by strengthening my skills in using Windows Powershell, learning how to use the platform Docker with Docker Compose, and learning how to migrate my application to the cloud service of Amazon Web Services (AWS).

Planning for future use of the application made in this course includes choosing containers or serverless. This choice depends on predictions on traffic usage because unpredictable traffic usage is better suited for serverless while containers are able to cost effectively handle consistent high usage. The scaling will be handled automatically with AWS, either up or down, and predicting costs are not easy due to the pay-as-you-go model but are highly cost effective due to not wasting capital on idle or unused services. For the particular project in this course I will recommend AWS for the traffic will not be consistently high.

I am in the beginning phase of software development having been introduced to and used the programming languages of Python, Java, and C++, along with use of HTML and XML, and building full stack applications.
